1 MR CLEAN-NO IV, Statistical Analysis Plan

- 2 Charles Majoie, Yvo Roos, Jonathan Coutinho, Bart Emmer, Kilian Treurniet, Natalie LeCouffe,
- 3 Manon Kappelhof, Hester Lingsma, Diederik Dippel, for the MR CLEAN-NO IV Steering Committee.
- 4 V2.0 January 16th 2021
- 5

6 Introduction

- 7 The aim of the MR CLEAN-NO IV: Intravenous treatment followed by endovascular treatment
- 8 versus direct endovascular treatment for acute ischemic stroke caused by a proximal

9 *intracranial occlusion* trial is to determine whether direct endovascular treatment (EVT)

- 10 compared to EVT preceded by intravenous alteplase administration (IVT) for patients with
- 11 acute ischemic stroke caused by an intracranial proximal large vessel occlusion in the
- 12 anterior circulation has a superior effect on functional outcome.
- 13 In this statistical analysis plan we describe the rationale behind the trial, the design of the
- 14 trial, the methodology to assure adequate blinding and the statistical procedures to
- 15 estimate the primary effect. Additionally, we predefine the most important subgroup
- analyses. Last, we specify the time-path after follow-up of the final patient to publication.
- 17 Please note that, due to word count restrictions, it is possible that not all pre-specified
- 18 analyses listed in this statistical analysis plan will be included in the publication on the
- 19 primary outcomes of the MR CLEAN-NO IV trial. Those subgroup analyses will be made
- 20 available in subsequent publications or online.
- 21

22 Rationale

23 Current European and North American guidelines currently state that all eligible patients 24 should receive IVT irrespective of whether they are eligible for EVT. As such, most patients treated with EVT are pre-treated with IVT.¹ However, the treatment effect, as estimated in 25 the HERMES pooling², of EVT in patients pre-treated with IVT was similar to patients who 26 27 were not pre-treated with IVT. No treatment effect modification was observed and effect estimates were comparable and statistically significant in both groups.² With faster and 28 more consistent recanalization rates of EVT, the value of pre-treatment with IVT is 29 30 questioned. The beneficial effect of IVT constitutes a trade-off between early recanalization 31 through lysis of the thrombus and an increased risk of hemorrhages .³ However,

recanalization rates of proximal large vessel occlusions are relatively low when treated only 32 33 with IVT, and spontaneous or IVT-induced reperfusion before EVT is only rarely observed.^{4–6} 34 Furthermore, the similar rates of symptomatic hemorrhage with and without EVT suggest that hemorrhage risk is primarily an adverse effect of IVT¹. Last, IVT administration could 35 predispose to thrombus fragmentation and distal migration, rendering retrieval of the 36 thrombus and reaching complete recanalization more difficult. Conversely, IVT might soften 37 38 the thrombus resulting in successful thrombectomy more often and IVT might lyse smaller distal thrombi caused by the intervention.⁷ More importantly, in patients with tortuous 39 40 vessels or tandem lesions, EVT may not be successful, leaving IVT as the only treatment 41 option. Finally, the recently published Direct MT trial compared Chinese patients eligible for 42 both EVT and IVT presenting at EVT capable centers and found that EVT only was noninferior to EVT preceded by IVT.⁸ As such, there currently is equipoise concerning the added 43 44 value of IVT in patients eligible for both IVT and EVT.

45

46 Status of the trial

47 As of this writing, a total of 20 centers have been initiated in the Netherlands, France and

48 Belgium. Patient enrollment was finished with the enrollment of the 540th patient on

49 October 28, 2020. The database will be locked in February 2021.

50

51 Research Questions

52 The primary objective is to determine whether direct EVT for patients with acute ischemic

53 stroke caused by an intracranial proximal large vessel occlusion in the anterior circulation is

54 superior to IVT directly followed by EVT in terms of functional outcome.

55

56 The secondary objective is to explore whether direct EVT for patients with acute ischemic

57 stroke caused by an intracranial proximal large vessel occlusion in the anterior circulation is

58 non-inferior to IVT directly followed by EVT regarding functional outcome.

59

60 The tertiary objective is to determine whether direct EVT for patients with acute ischemic

61 stroke caused by an intracranial proximal large vessel occlusion in the anterior circulation

62 has a beneficial effect on safety with regard to the occurrence of embolic, ischemic or

63 hemorrhagic complications compared to IVT directly followed by EVT. Furthermore, the

- 64 effect on early reperfusion before thrombectomy, reperfusion after thrombectomy,
- 65 recanalization on follow-up imaging, final lesion size, follow-up stroke severity, and
- 66 mortality will be assessed.
- 67

68 Trial Design

69 MR CLEAN-NO IV (ISRCTN80619088) is an international multicenter clinical trial with 70 randomized treatment allocation, open label treatment, and blinded endpoint evaluation 71 (PROBE design). The treatment contrast in the study is direct EVT compared to IVT directly 72 followed by EVT (direct EVT compared to IVT+EVT). The intravenous treatment is alteplase 73 in a dose of 0.9 mg/kg, of which 10% is administered as a bolus and 90% by infusion during 1 74 hour. Endovascular treatment has to be mechanical, with stent-retriever thrombectomy as 75 the first treatment modality. Suction and other devices are preferred as rescue devices. 76 Only CE-marked devices are allowed for use in the trial. Randomization is stratified by 77 center and, for participating centers in the Netherlands, by inclusion in the active treatment 78 arm of the Multicenter Randomized trial of Acute Stroke treatment in the Ambulance with a 79 nitroglycerin Patch (MR ASAP). In MR ASAP, the effect on functional outcome of prehospital 80 transdermal nitroglycerin treatment within 3 hours of ischemic or hemorrhagic stroke onset 81 is determined (http://www.mrasap.nl, ISRCTN99503308). In the Netherlands, participation 82 in the ARTEMIS project was not considered an exclusion criterium. In ARTEMIS, patients were randomized into a group with real-time feedback to the physicians on the times from 83 84 admission to administration of alteplase and time to groin puncture, or into a group without 85 direct feedback (https://clinicaltrials.gov/ct2/show/NCT02808806). 86 Inclusion criteria 87

88 – Clinical diagnosis of acute ischemic stroke
 89 – Proven proximal intracranial occlusion on CTA/MRA (ICA-T, M1 or proximal
 90 M2)
 91 – Start of IVT possible within 4.5h after symptom onset
 92 – National Institutes of Health Stroke Scale (NIHSS) score ≥ 2

3

93	— Age ≥ 18 years
94	 Deferred informed consent
95	
96	Exclusion criteria
97	 Pre-stroke score on the modified Rankin Scale >2
98	 Any contra-indication for IVT, per international guidelines:
99	 arterial blood pressure exceeding 185/110 mmHg
100	 blood glucose level less than 2.7 or over 22.2 mmol/L
101	 cerebral infarction in the previous 6 weeks with residual neurological
102	deficit or signs of recent infarction on neuro-imaging
103	 recent head trauma
104	 recent major surgery or serious trauma
105	 recent gastrointestinal or urinary tract hemorrhage
106	 previous intracerebral hemorrhage
107	 use of anticoagulant with INR exceeding 1.7
108	 known thrombocyte count less than 100 x 109/L
109	 treatment with direct thrombin or factor X inhibitors, treatment with
110	therapeutic dose of (low-molecular weight) heparin.
111	 participation in medical or surgical intervention trials other than
112	current, with the exception of the Multicenter Randomized trial of
113	Acute Stroke Treatment with a nitroglycerine patch
114	(http://www.mrasap.nl, ISRCTN99503308) and ARTEMIS trials
115	(https://clinicaltrials.gov/ct2/show/NCT02808806).
116	
117	Outcomes
118	The primary outcome is the score on the modified Rankin Scale at 90 days +/- 14 days after
119	randomization.
120	
121	Secondary outcomes are:
122	- Pre-interventional recanalization
123	- Reperfusion grade (eTICI score) on final DSA after EVT;

124	- Recanalization rate at 24 hours (\pm 12 hours), assessed with CTA or TOF-MRA;
125	- NIHSS score at 24 hours and 5-7 days, or at discharge;
126	- Follow-up lesion volume, assessed with NCCT at 5-7 days, or assessed at 24 hours
127	(±12 hours) with MRI;
128	- The following dichotomizations of the mRS at 90 days (± 14 days):
129	o 0-1 vs. 2-6
130	o 0-2 vs. 4-6
131	• 0-3 vs. 3-6
132	- Score on the EQ-5D-5L and Barthel index at 90 days (± 14 days).
133	
134	Safety outcomes include:
135	 Intracerebral hemorrhage according to the Heidelberg Bleeding Classification⁹;
136	 sICH scored according to the Heidelberg Bleeding Classification;
137	 Occurrence of aneurysma spurium;
138	 Occurrence of groin hematoma;
139	 Embolus in new territory on DSA during EVT;
140	$-$ Infarct in a new territory within 5-7 days assessed with NCCT or 24 hours (\pm 12
141	hours) assessed with DWI-MRI;
142	 Death from all causes within 90 days
143	
144	Blinding
145	The trial features a PROBE design. Both patient and treating physician will be aware of the
146	treatment allocation. Trained research personnel unaware of treatment allocation will
147	assess information on outcome at three months using standardized forms and procedures

147 assess information on outcome at three months using standardized forms and procedures

148 during a telephone interview. Final assessment of the mRS score at 90 days will be performed by the outcome committee, consisting of trained investigators blinded to the 149 150 treatment allocation, based on the masked reports of the telephone interview. 151 Neuroimaging will be assessed by a core laboratory blinded for treatment allocation. Information concerning treatment allocation will be kept separate from the 90-day follow-152 153 up outcome database. The steering committee will be kept unaware of the results of safety 154 assessments and interim analyses. An independent trial statistician will combine data on 155 treatment allocation with the clinical and outcome data to report summaries of trial 156 progress, regular safety assessments, and interim analyses on efficacy and safety to the data 157 safety monitoring board (DSMB).

158

159 Missing data and death

160 We will report proportions of missing values for all collected variables. For descriptive

analyses, only the crude, non-imputed data will be presented. For the regression analyses,

162 missing data (if any) will be imputed using multiple imputation methods. For patients who

died within the study period we will assign the worst score for all unassessed clinical

164 outcome measures and use those for analyses.

165

166 Time path of the analysis and locking of the database

After the follow-up of the final patient, the last records of the database will be cleaned and
checked for completeness within one month. Upon completion, the database will be locked.
The data will be sent to the independent trial statistician who will perform the final analysis.
The final results will then be shared for consideration with the steering committee of the
trial. Within 3 months after obtaining the final results, a manuscript describing the main

- 172 results of the trial will be submitted for publication.
- 173

174 Statistical Analysis

175 Primary effect analysis

176 A direct comparison between the two trial arms will be made concerning the score on the

177 mRS at 90 days after randomization. This will be an intention to treat analysis. The primary

178 effect parameter will be the odds ratio of a shift in the direction of better outcome on the

179	full mRS with its 95% confidence interval. A p-value will also be presented. The odds ratio is
180	estimated with ordinal logistic regression. To increase the power of the study ^{10,11} , the
181	primary, secondary and tertiary analyses will all be adjusted for the following major
182	prognostic variables:
183	- age
184	- baseline NIHSS
185	- collateral status
186	- pre-stroke mRS
187	- time from onset to randomization
188	
189	Primary effect analysis in subgroups
190	To explore whether the treatment effect is homogeneous across subgroups, we have
191	predefined the following subgroups in which the primary analysis will also be performed:
192	- Tertiles of age
193	- Tertiles of baseline NIHSS
194	- Tertiles of the time from symptom onset to randomization
195	- Occlusion location (ICA-T vs M1 vs M2).
196	- Presence of tandem lesion, yes or no (defined as an ipsilateral significant
197	atherosclerotic stenosis, atherosclerotic occlusion, or dissection combined with
198	intracranial proximal occlusion)
199	- Thrombus perviousness, in tertiles of the measured thrombus attenuation increase
200	on CTA compared to NCCT at baseline ¹²
201	- Collateral status
202	- History of atrial fibrillation
203	- MR ASAP inclusion status
204	Ordinal regression models adjusted for the same variables as the primary analysis, with and
205	without a multiplicative interaction term of the abovementioned variables and the
206	treatment allocation, will be compared to determine whether the added interaction term
207	significantly improves model fit. In the interest of statistical power, for the subgroups that
208	are based on a continuous variable, the continuous variable will be used in the statistical
209	analysis of interaction with treatment (e.g. the whole range of age instead of a
210	trichotomized variable). Statistical significance is defined by p <0.05.

211

242

212 Secondary, tertiary and safety analyses For the secondary effect analysis, non-inferiority of direct EVT compared to IVT+EVT will be 213 214 assessed in an intention to treat analysis. Direct EVT is non-inferior to IVT+EVT if the lower 215 boundary of the 95% confidence interval of the odds ratio for a shift in the direction of 216 better outcome on the mRS determined at 90 days, estimated as described under 'primary 217 effect analysis' does not cross the pre-defined non-inferiority boundary of 0.8. 218 219 For the tertiary analyses all secondary and safety outcomes as listed above will be compared 220 between the trial arms in an intention to treat fashion. 221 222 For dichotomous outcomes, binary logistic regression will be used to estimate an odds ratio. 223 For continuous outcome measures, log transformation will be used if necessary, to correct 224 for non-normally distributed data, and regression beta coefficients are reported as 225 estimated with linear regression. Again, all analyses will be adjusted for the major 226 prognostic variables age, baseline NIHSS, pre-stroke mRS score, collateral status, and time 227 from onset to randomization. To express statistical uncertainty, 95% confidence intervals 228 will be reported for all analyses. P-values will be presented for all tertiary analyses. 229 230 As-treated analyses 231 In addition to the intention to treat analyses, the primary outcome (mRS at 90 days), 232 secondary, and safety outcomes will also be analyzed in an as-treated population. 233 234 The as-treated population consists of the following patients: All patients allocated to IVT+EVT who received the full intended dose of intravenous 235 236 alteplase. • Patients randomized to IVT+EVT in whom successful reperfusion was 237 238 achieved before completion of alteplase infusion, in whom the infusion was 239 subsequently stopped are an exception. These patients are also included in 240 the as-treated analysis as this might reflect future clinical practice. 241 All patients allocated to direct EVT who did not receive any intravenous alteplase prior to start of EVT. Patients who were randomized to direct EVT and who received

- 243 intravenous alteplase after EVT because of incomplete reperfusion, are included in
- the as-treated analysis, since administration of IVT after failed EVT was part of the 244
- 245 strategy of direct EVT. Exclusion of these patients would also bias the analysis in
- 246 favor of direct EVT.
