### Study objectives

The traditional model of antenatal care often involves 14 or more clinical visits but there is large practice variation. The detection of hypertension is an important function of antenatal care and, unless blood pressure can be monitored outside the clinic, this sets a lower limit on the frequency of visits. We propose a pilot study (prior to embarking on a larger trial) where women would be randomised to receive EITHER routine antenatal visits and clinic monitoring of blood pressure OR a reduced number of antenatal visits and home monitoring of blood pressure. The pilot will investigate what proportion and types of women are willing to take part in such a study and whether women use portable blood pressure monitors satisfactorily and at the prescribed times. It will also be sufficient to measure major effects on anxiety and number of attendances.
