Study information

Scientific Title

Study objectives

There is little evidence for effectiveness of cardiac rehabilitation following acute myocardial infarction as currently provided in the NHS and in the context of modern therapeutic practice. There are few recent trials and historic trials may be of little relevance, since treatments in cardiac care units, with thrombolysis, aspirin, β blocker, ACE inhibitor and statins have changed greatly in the past thirty years.

The principal objective was to determine the effectiveness of programmes of cardiac rehabilitation, as currently provided and in the current clinical context. The trial aimed to measure the effect of rehabilitation on mortality, morbidity and quality of life of patients following myocardial infarction. Further aims included identification of programmes that are more or less effective and of characteristics of patients who benefit more or less from cardiac rehabilitation and to estimate costs of cardiac rehabilitation.

Participant information sheet

Health condition(s) or problem(s) studied

Cardiovascular diseases: Heart disease

Interventions

1. Comprehensive cardiac rehabilitation
2. Standard care

Intervention Type

Other

Phase

Not Specified

Primary outcome measure

Outcomes at one year included mortality, morbidity, cardiac medication, health service use, psychological wellbeing and quality of life on standard scales, cardiac risk factors, including smoking, drinking, diet and leisure time activity.

Secondary outcome measures

Not provided at time of registration

Overall study start date

01/04/1996

Completion date

01/04/2000

Eligibility**Key inclusion criteria**
