# Study information

#### Scientific Title

# **Study objectives**

A sustained natureal apophyseal glide (SNAG) is a technique widely used by physiotherapists to treat patients with neck problems, however, its efficacy in comparison with the standard treatment of exercise is unknown. This study intends to establish which physiotherapy modality is better in improving neck pain. There is a lot of conjectural evidence from the author of the SNAG and case studies. But the technique has not been subjected to the rigorous testing of a randomised clinical trial.

Musculoskeletal Diseases: Neck problems

#### Interventions

This is to find out if SNAG technique has improved neck exercise. The purpose of the study is to compare two physiotherapeutic techniques to establish which is better in improving pain, stiffness and disability in patients with neck pains. All the patients assessment will take place within the same physiotherapy department by the same physiotherapist. Baseline characteristics of each group will be monitored for age, sex whether the cause of their pain is known or unknown and the length of time of their pain to minimise confounding variables. If a diagnosis of mechanical neck pain is made, and if they meet the inclusion/exclusion criteria they will be asked if they would like to participated in the study. All patients will be given a patient information

sheet to take home and read and consult with relatives for a minimum of 48 hours. If they agree to take part in the study they will be asked to sign a consent form. The outcome measures process may take approximately 10 minutes.

Following completion of the 8 week study period if the patients symptoms have not resolved they will receive any other appropriate treatment as necessary with the physiotherapist otherwise they will be discharged.

# Intervention Type

Other

#### Phase

**Not Specified** 

# Primary outcome measure

A change in neck range of motion, measured in degrees and after treatment interventions.

# Secondary outcome measures
