Study design
Randomised controlled trial

Primary study design
Interventional

Study type(s)
Treatment

Health condition(s) or problem(s) studied
Signs and Symptoms: Pain

Interventions
The effects of the three formulations of this anaesthetic agent will be studied as the patient goes to sleep in the usual way for their operation. We will randomly allocate subjects into three groups prior to receiving the induction agent and injection pain will be evaluated by subjective and objective scoring of pain as they go to sleep. Intravenous canulation will be via a vein on the dorsum of the hand. After a small dose of the drug, they will be asked by the anaesthetist(s) about any soreness in their arm and to rate this as none, mild, moderate or severe. The anaesthetic and operation will proceed in the usual way after this.

Intervention Type
Drug

Phase
Not Applicable

Drug/device/biological/vaccine name(s)
Propofol-Lipuro

Primary outcome(s)
The outcome measure is reduction of injection pain on induction of anaesthesia with a very commonly-used agent. Although Lipuro has been subject to clinical trials during its development, it has not been compared to other formulations in this way previously.

Key secondary outcome(s))
