Plain English summary of protocol

Background and study aims

Floaters are small, semi-transparent specks or shapes that appear to float across a person's field of vision. They may look like dots, threads, or cobwebs and are most noticeable when looking at a bright background, such as a blue sky or a white wall. Floaters are actually tiny clumps of gel or cells that cast a shadow on the retina (the light-sensitive layer at the back of the eye), causing them to be visible. While they are generally harmless, floaters can sometimes be bothersome or interfere with clear vision.

The purpose of this study is to evaluate the efficacy and safety profile of a specific laser treatment to split floaters which are perceived by patients as bothersome into smaller pieces

Who can participate?

Anyone aged 18 years and above who is complaining of bothersome floaters in either one or both eyes. In the latter case, the retina specialist will determine which of the two eyes will be treated as part of this study.

What does this study involve?

An initial visit to The Retina Clinic London to determine suitability for this study by thoroughly screening the patient's eyes (baseline visit). If suitable, the patient will be offered laser treatment of his/her floaters in one eye. After treatment, the patient will be asked to come back to The Retina Clinic London for follow-up visits including the same testing regimen as at the baseline visit, at months 3, 6 and 12.

What are the possible benefits and risks of participating?

The possible benefits for the patients who suffer from bothersome floaters in their vitreous to improve visual function, quality of life and mental health.

Possible risks: We expect any risk to the patient's eye to be negligible. To avoid collateral damage, eyes will only be included in this study where the posterior vitreous interface is shown to be a minimum of 3mm from the retinal surface as measured by ultrasound and/or OCT, and

where the posterior vitreous is 6mm from the lens (1.5 lens thickness) anterior to which no floaters will be treated. The surgeon will employ a pulse offset of 300 microns (which delivers the actual laser shockwave either behind, or in front of the focusing target, depending on the setting) to further amplify this safety zone: anteriorly offset (i.e. in front of the focusing target) for floaters located anterior to the mid vitreous and posterior offset (i.e. behind the focusing target) for floaters located posterior to the mid vitreous. There will be no offset used for floaters in the mid vitreous. Energy used will range between 1.5 and 5.0 mJ per single pulse with a recommended maximum total energy dose of 1,600 mJ applied per session. Energy of 5.0 mJ is only to be used when treating floaters in the mid vitreous and lower settings should be used closer to the retina or the lens.

Where is the study run from?
The Retina Clinic London (UK)

When is the study starting and how long is it expected to run for?
January 2023 to December 2026

Who is funding the study?
The Retina Clinic London (UK)

Who is the main contact?
Dr Paulo E Stanga, p.stanga@theretinacliniclondon.com

Study information**Scientific Title**

Effect of YAG laser vitreolysis on vitreous structure and visual function in patients with vision degrading myodesopsia secondary to myopic vitreopathy or posterior vitreous detachment

Acronym

YVL Laser Study

Study objectives

The aim of the study is to determine the safety and efficacy of Nd:YAG laser treatments for VDM in eyes with vitreous opacities due to MV and PVD. It is hypothesised that there will be a positive correlation between changes in objective measures of vitreous opacities and functional outcomes pre- and post- laser. It is further hypothesised that patients suffering from VDM may have improvements in visual function as well as quality-of-life after laser treatment(s) that correspond to a quantitative decrease in the size and/or number of vitreous opacities post-treatment. Lastly, it is hypothesised that Nd:YAG laser vitreolysis will be more effective in eyes with PVD than in eyes with MV.

Health condition(s) or problem(s) studied

Treatment of floaters in the vitreous in patients with bothersome symptoms

Interventions

Only patients with bothersome floaters will be recruited for this study. They will undergo the following testing regimen:

1. Visual Function testing using the ETDRS eye charts: Visual Acuity logMAR Best-Corrected Visual Acuity (BCVA) and Low Luminance Best-Corrected Visual Acuity (LL-BCVA).
2. Reading function assessment using the hand-held MNREAD chart.
3. Visual Function Questionnaire using the 39-item National Eye Institute Visual Function Questionnaire (NEI VFQ-25 + Optional Items).
4. VFFQ (Vitreous Floaters Functional Questionnaire).
5. High-Definition Analyser (HDA)
6. Light Distortion Analyser (LDA)
7. C-Quant

8. Contrast Sensitivity Function test using the Freiburg Acuity Contrast Test (FrACT).
9. Ultrasonography (ABSolu 20MHz annular array).
10. Electroretinography (ERG) using the RETeval® Hand-Held, Full-Field ERG.
11. Optos Multiwavelength and Autofluorescence Ultra widefield Imaging: Central with Steering.
12. Widefield spectral domain optical coherence tomography scan (WF SD-OCT) centered on the fovea.
13. Slit lamp Biomicroscopy.
14. Microperimetry.
15. Indirect Ophthalmoscopy with 360-degree scleral indentation.

Eyes will only be included in this study where the posterior vitreous interface is shown to be a minimum of 3 mm from the retinal surface as measured on ultrasound and/or OCT, and where the posterior vitreous is 6 mm from the lens (1.5 lens thickness) anterior to which no floaters will be treated.

Before the procedure, the pupil is dilated with 1% Tropicamide and 2.5% Phenylephrine and the surface of the eye is anesthetised using 0.4% Oxybuprocaine Hydrochloride. Then, the contact lens is placed on the eye. Under direct observation with a slit lamp biomicroscope using coaxial illumination, the laser is brought to focus upon the opacities in the vitreous body. Opacities to be treated are selected with a minimum distance of 3 mm from the retina and 6 mm from the lens to safeguard against untoward effects upon the lens anteriorly and the retina and optic disc posteriorly.

The surgeon will employ a pulse offset of 300 microns to further amplify this safety zone: anteriorly offset for floaters located anterior to the mid vitreous and posterior offset for floaters located posterior to the mid vitreous. There will be no offset used for floaters in the mid vitreous.

Nanosecond pulses of laser with minimum levels of energy will be applied and increased as needed to achieve photo disruption of vitreous opacities. Energy used will range between 1.5 and 5.0 mJ per single pulse with a recommended maximum total energy dose of 1,600 mJ applied in a session.

Energy of 5.0 mJ is only to be used when treating floaters in the mid vitreous and lower settings should be used closer to the retina or the lens.

Intervention Type

Procedure/Surgery

Primary outcome measure

Floater location, density, and acoustic scatter measured using quantitative ultrasound imaging, before and after YAG laser vitreolysis

Secondary outcome measures

Measured at baseline, 3 months, 6 months, 12 months:

1. Visual Acuity (ETDRS LogMAR)
2. Near Visual Acuity
3. Visual Function Questionnaire (VFQ-25)
4. Vitreous Floater Functional Questionnaire (VFFQ)
5. Contrast Sensitivity Function (CSF)
6. Quantitative Ultrasonography (B-Scan)
7. Electroretinography (ERG)
8. Optos Multiwavelength and Autofluorescence Ultrawidefield Imaging
9. Optical Coherence Tomography (OCT)
10. Microperimetry (MP)

- 11. Indirect Ophthalmoscopy with 360 Degree Scleral Indentation
- 12. High Definition Analyser (HDA)
- 13. Light Distortion Analyser (LDA)
- 14. C-Quant

Overall study start date

01/01/2023

Completion date

05/12/2026

Eligibility

Key inclusion criteria

- 1. Able and willing to give informed consent.
- 2. Age ≥ 18 years
- 3. Suffering from symptomatic vitreous floaters visible on contact lens biomicroscopy in one or both eyes.
- 4. Floaters arising from either/both:
 - 4.1. Myopic vitreopathy
 - 4.2. Posterior vitreous detachment

Participant type(s)

Patient

Age group

Adult

Lower age limit

18 Years

Upper age limit

100 Years

Sex

Both

Target number of participants

50

Key exclusion criteria

- 1. Present with vitreous opacities outside of the described safety area described in section 3.1.1 (i.e., 3 mm vicinity of the retina and 6 mm vicinity of the lens).
- 2. Visually significant cataract that either causes sufficient media opacity to reduce quality of imaging or would require surgery during the study follow up period.
- 3. High risk of peripheral lesions requiring treatment at the discretion of the local PI during the study period (if patients require and receive treatment for these at screening, they may be rescreened after 2 months following procedure, at the discretion of the PI).
- 4. Vitreous floaters or PVD symptoms present for less than three months.
- 5. Unable to attend study appointments.

6. Synchysis scintillans.
7. Asteroid hyalosis.
8. Vitreous haemorrhage.
9. Active photopsia.
10. Active uveitis.
11. Active proliferative diabetic retinopathy, and/or other significant retinal vascular pathology
12. Pre-existing visual field loss (including uncontrolled glaucoma).
13. Inherited retinal diseases.
14. History of, or active ocular trauma/penetrating ocular injury.
15. Any significant vitreoretinopathy e.g., current or previous retinal detachment, epiretinal membrane, macular hole.
16. History of previous YAG laser vitreolysis treatments, or previous vitreoretinal surgery for any condition (such as retinal detachment, proliferative diabetic retinopathy).
17. History of complicated cataract surgery (e.g anterior vitrectomy).
18. History of intraocular surgery within 6 months from starting the study.
19. Any other significant ocular or non-ocular condition that, at the discretion of the local PI, puts the subject at risk or influences the results of the study.
20. Patients who, in the opinion of the investigator, would be unwilling or unable to provide written informed consent, or undergo the testing procedures as described in the protocol.
21. Pregnant or breastfeeding women

Results and Publications

Publication and dissemination plan

This study will collect data over a period of two years in order to gain new insight into ultrasound imaging and its relation to treatment of VDM. At the end of the two years, following data analysis, we will aim to publish the data and study findings in ophthalmic peer-reviewed journals.

Intention to publish date

01/03/2027

Individual participant data (IPD) sharing plan

The data-sharing plans for the current study are unknown and will be made available at a later date. Currently, due to patient confidentiality, we do not plan to share the data of the individual patients.

IPD sharing plan summary

Not expected to be made available, Data sharing statement to be made available at a later date
