Study information

Scientific Title

A comparison of pre-medication with oral paracetamol versus intravenous paracetamol given at time of induction for post-operative analgesia following wisdom tooth extraction

Study objectives

There is no clinically significant difference between the post-operative analgesic effects of paracetamol when given orally as a pre-medication one hour pre-operatively, and when given as an intravenous infusion immediately pre-operatively.

Ethics approval required

Old ethics approval format

Ethics approval(s)

Brighton East Research Ethics Committee approved as of 19th February 2008 (ref: 08/H1107/16)

Study design

Randomised, controlled, blinded trial

Primary study design

Interventional

Study type(s)

Treatment

Health condition(s) or problem(s) studied

Analgesia in wisdom tooth extraction

Interventions

Participants will be randomly assigned to either:

- 1. Oral pre-med group: two 500 milligram paracetamol capsules and 100 ml bag of normal saline for injection, or
- 2. IV group: two placebo lactose capsules and 100 ml (1 gram) of paracetamol for injection

The oral pre-medication will be given one hour prior to surgery and the intravenous whilst the participant is under a general anaesthetic. Duration of treatment 15 minutes for intravenous injection. Duration of follow up until discharged from hospital (max 3 - 4 hours).

Intervention Type

Drug

Phase

Drug/device/biological/vaccine name(s)

Paracetamol

Primary outcome(s)

We will compare the pain scores of patients in the two study arms one hour post-operatively. This will be done in recovery using a Visual Analogue Scale (VAS) pain scoring system.

Key secondary outcome(s))

We will compare the time to request of post-operative rescue analgesia between the two study arms. Specifically, this will be measured from when the patient arrives in recovery. This point will serve as a standard time zero (t0). The time elapsed before the patient requests additional analgesia (if at all) will act as a secondary surrogate marker of analgesic efficacy.

Completion date

31/12/2008

Eligibility

Key inclusion criteria

Patients over 18 years (either sex) having a general anaesthetic for extraction of wisdom teeth of which at least one must be a lower molar tooth.

Participant type(s)

Patient

Healthy volunteers allowed

No

Age group

Adult

Lower age limit

18 years

Sex

All

Key exclusion criteria

- 1. Patients who are unable to give full consent, or who do not wish to take part in the trial
- 2. Patients who have a baseline Visual Analogue Scale (VAS) score of more than zero
- 3. Patients unable to swallow tablets
- 4. Patients who have taken simple analgesics that day, prior to surgery
- 5. Hypersensitivity or history of serious adverse reactions to paracetamol or non-steroidal antiinflammatory drugs
- 6. Active liver disease
- 7. Renal dysfunction
- 8. Pregnant or breast feeding women
- 9. Alcohol or drug abuse
- 10. History of unresponsiveness to paracetamol
- 11. Gastric or peptic ulcer disease
- 12. Inflammatory bowel disease
- 13. Blood coagulation abnormalities
