Plain English summary of protocol

Background and study aims

Renal artery stenosis (RAS) is a narrowing of the arteries that carry blood to one or both of the kidneys. It is associated with an increased risk of high blood pressure and progression of kidney disease. However, in clinical practice, the presence of renal artery stenosis may be difficult to distinguish in patients with type 2 diabetes with kidney disease. This study was designed to find out about the prevalence of previously undetected renal artery stenosis in a group of South Asian patients with type 2 diabetes undergoing angiography for investigation of heart disease, and to find clinical characteristics that may aid in the identification of these patients.

Who can participate? Patients with type 2 diabetes who are undergoing coronary angiography.

What does the study involve?

All recruited patients will have a renal angiography carried out at the same sitting as a coronary angiography.

What are the possible benefits and risks of participating? There will be no immediate direct benefit to those taking part.

Where is the study run from? Inlaks & Budhram Hospital, Pune, India.

When is the study starting and how long is it expected to run for? The study started in January 2008 and ended in December 2008.

Who is funding the study? Inlaks & Budhram Hospital, Pune, India

Who is the main contact? Dr Eberta Tan Eberta_Tan@cgh.com.sg

Study information

Scientific Title Prevalence and risk factors of renal artery stenosis in South Asian patients with type 2 diabetes using renal angiography

Study objectives To determine the prevalence and risk factors of renal artery stenosis (RAS) in patients with type 2 diabetes.

Ethics approval required Old ethics approval format

Ethics approval(s) Institutional Board of Inlak Budhram Hospital, Pune, India, December 2007

Study design Cohort study

Primary study design Observational

Secondary study design Cohort study

Study setting(s) Hospital

Study type(s)

Screening

Health condition(s) or problem(s) studied

Renal artery stenosis in patients with type 2 diabetes

Interventions

Statistical analysis

The characteristics of patients with RAS were compared to those without RAS using Student's ttests for continuous variables and Chi-Square or Fisher tests for comparison of categorical variables as appropriate. Univariate logistic regressions were performed to identify the factors associated with the presence of RAS. From the significant variables identified at this step, the backward stepwise method was used to identify variables that were independently associated with the outcome using the likelihood ratio test. Odds ratios and their corresponding 95% confidence intervals were presented as effect size. Tests for the appropriate assumptions for the models were carried out. Data was analyzed using SAS v9.2 (SAS Institute Inc., Cary, NC, USA) and the level of significance was set at 5%.

Total duration of follow-up: 1 day

Intervention Type Other

Phase Not Applicable

Primary outcome measure Prevalence of renal artery stenosis

Secondary outcome measures Risk factors of renal artery stenosis

Overall study start date 01/01/2008

Completion date 31/12/2008

Eligibility

Key inclusion criteria

All consecutive patients with type 2 diabetes who underwent coronary angiography and who gave informed consent to be screened for renal artery stenosis at the same time were recruited

into the study. The decision for coronary angiography was made by the consulting cardiologist based on a clinical indication of either symptomatic angina, ST-T alterations on the electrocardiogram or an acute myocardial infarction.

Participant type(s)

Patient

Age group

Adult

Sex Both

Target number of participants 249

Key exclusion criteria

Patients with known vasculitis
 Renal artery stenosis
 A serum creatinine level of >3.0 mg/dl or on renal replacement therapy

Date of first enrolment

01/01/2008

Date of final enrolment 31/12/2008
