Plain English summary of protocol

Background and study aims

Secondary spontaneous pneumothorax (SSP) is a medical emergency where an abnormal collection of air develops in the space between the lung and the chest wall, causing lung collapse. This occurs in patients with existing lung diseases such as chronic obstructive pulmonary disease (COPD). In the UK, patients with SSP are usually treated by inserting a drain into the chest to remove the air. The drain is stitched in place and left until the air is completely removed. The drain typically remains in place for over a week, leading to long hospital stays. Sometimes these patients need surgery to help stop the air leaking into the lung, but it is also recognised that these patients may not be fit for major surgery. Unfortunately, we don't have data from UK patients about the key consequences of developing a secondary spontaneous pneumothorax. For example, we don't know how long patients stay in hospital, how many go for surgery, and how many develop complications. With this information we can better plan for care, but also look at why some patients stay longer in hospital and why some patients need surgery, whilst others don't. The aim of this study is to gather information about SSP in an attempt to answer some of these unknown questions. We will recruit patients admitted to hospital with SSP throughout the UK over a period of 1 year. We will collect routine data from the patient's records, such as age, medical history and how long they stay in the hospital.

Who can participate?

Any patient with a collapsed lung with known or suspected underlying lung disease OR who is over the age of 50 with a significant smoking history is eligible to participate in this study. Patients with a collapsed lung because of an injury or a medical intervention are not eligible.

What does the study involve?

This is an observational study, which means that nothing additional is required from participants outside of their routine care. They will be informed about the study and given the option to decline to participate. The study team will collect data on the patients' background, their medical history, whether they are or have been a smoker, how fit the patient is and data related to their collapsed lung and how it is managed. Further data will then be collected at 1 month and 6 months post-enrolment. There are no additional interventions required.

What are the possible benefits and risks of participating?

There are no direct clinical benefits to participants from engaging in this research as it is observational. Once the results are published, we hope that the knowledge obtained will benefit patients in the future by helping clinicians understand better how to manage patients with this condition, taking into account different factors that may influence their outcomes. The observational nature of this study means that there are no additional risks to patients from participating.

Where is the study run from?

The lead site is North Bristol NHS Trust (UK)

When is the study starting and how long is it expected to run for?

May 2022 to September 2024

Who is funding the study?

Rocket Medical Plc (UK)

Who is the main contact?

Dr Eleanor Barton, eleanor.barton@nbt.nhs.uk (UK)

Secondary spontaneous pneumothorax

Interventions

Patients presenting with secondary spontaneous pneumothorax (SSP) to any of the hospitals involved in the study will be screened and invited to participate in the study by trained clinicians or research nurses. SSP is defined in this study as a spontaneous pneumothorax with no history of trauma or iatrogenic intervention preceding it in a patient with known or suspected lung disease or a patient over the age of 50 with a smoking history. Patients with SSP will almost exclusively require admission under a specialist respiratory team, and as such we anticipate high patient identification rates.

We will collect data on the patient's demographics, past medical history and history of current illness, smoking status including cannabis, asbestos and other inhalational exposures, clinical frailty score (CFS) and performance status (PS). We will also collect data related to the pneumothorax and its management (e.g. digital or analogue assessment of air leak, size of the pneumothorax on CXR, procedures performed and their outcomes).

Further data will be collected from the patient's medical records at 1 month and 6 months post

enrolment, to encompass the patient's length of stay, number and type of interventions, recurrence, and mortality. These two-time points allow for the collection of complete data sets, acknowledging that some patients may have a prolonged stay exceeding 1 month and ensuring that enough time has elapsed to capture the incidence of recurrence.

Intervention Type

Other

Primary outcome(s)

1. Patient demographics: age (years), gender (M/F), socioeconomic status (Index of multiple deprivations) measured from the patient's medical records at baseline
2. Number and type of procedures required (number, procedures performed) measured from the patient's medical records at baseline, 1 month and 6 months
3. Outcomes: Length of stay (days), air leak duration (days), mortality (death rate) measured from the patient's medical records at baseline, 1 month and 6 months

Key secondary outcome(s)

There are no secondary outcome measures

Completion date

30/09/2024

Eligibility

Key inclusion criteria

1. Emergency attendance to hospital with secondary spontaneous pneumothorax (SSP), confirmed by radiology, with SSP defined as spontaneous pneumothorax in presence of known or suspected lung disease OR spontaneous pneumothorax
2. Aged ≥ 50 years old
3. History of smoking

Participant type(s)

Patient

Healthy volunteers allowed

No

Age group

Mixed

Lower age limit

16 years

Upper age limit

50 years

Sex

All

Total final enrolment

Key exclusion criteria

1. Aged <16 years old
2. Iatrogenic pneumothorax
3. Traumatic pneumothorax

Date of first enrolment

15/02/2023

Date of final enrolment

31/03/2024
