Plain English summary of protocol

Background and study aims
Gliomas are brain tumours that start in glial cells. In children and adolescents diagnosed with gliomas, MRI scans are used to follow up patients which can be challenging, particularly when assessing a non-enhancing tumour. APT-CEST is a technique that can show an increased signal in non-enhancing parts of the tumour and the aim of this study is to correlate the APT-CEST signal with choline uptake as a marker of tumour activity.

Who can participate?
Children and adolescents aged 12-20 years being treated for glioma

What does the study involve?
Participation will involve the patient undergoing a PET-MRI scan. The participant will be injected with a radio-isotope named choline followed by an MRI scan. The MRI will be slightly longer than a normal diagnostic MRI at about 45 minutes. Following the PET-MRI scan, the patient will be free to go and will be followed up in clinic with their normal doctor.

What are the possible benefits and risks of participating?
The benefit for the patient will be an improved understanding of their tumour. The study will require extra time for scanning.

Where is the study run from?
University College London Hospitals NHS Foundation Trust (UK)

When is the study starting and how long is it expected to run for?
September 2015 to March 2020

Who is funding the study?
UCLH Biomedical Research Centre (UK)

Who is the main contact?
Dr Harpreet Hyare
harpreet.hyare@nhs.net

Study information

Scientific Title
Feasibility of amide proton transfer chemical exchange saturation transfer in paediatric, teenage and young adult gliomas

Study objectives
Amide proton transfer (APT)-chemical exchange saturation transfer (CEST) demonstrated an elevated signal in brain tumours compared to normal-appearing brain tissue.

Ethics approval required
Old ethics approval format

Ethics approval(s)
Approved 22/02/2016, London-Bromley Research Ethics Committee (Level 3, Block B, Whitefriars, Lewins Mead, Bristol, BS1 2NT, UK; +44 (0)207 104 8105; bromley.rec@hra.nhs.uk), REC ref: 16/LO/0276

Study design
Observational feasibility study

Primary study design
Observational

Study type(s)
Diagnostic

Health condition(s) or problem(s) studied

Glioma

Interventions
The participant is recruited from clinic by their normal doctor and is asked to undergo a PET-MRI study. The patient is given an information sheet and If the patient agrees, they are booked for a scan in the Nuclear Medicine Department. On the day of the scan, the patient is consented. The patient will have a canal fitted and be injected with radioactive choline. After 60 minutes, they will undergo a PET-MRI scan which is slightly longer than a normal MRI scan at approximately 45 minutes. The patient is then free to go and will be followed up by their normal doctor in clinic.

Intervention Type
Other

Primary outcome(s)
Glioma tumour cell proliferation measured using amide proton transfer chemical exchange saturation transfer (APT-CEST) and 18F-fluoromethylcholine (18F-choline) positron emission tomography (PET) standardised uptake value (SUV) at baseline

Key secondary outcome(s))
There are no secondary outcome measures

Completion date
01/03/2020

Eligibility

Key inclusion criteria
Patients aged 12-20 years undergoing treatment for glioma

Participant type(s)
Patient

Healthy volunteers allowed
No

Age group
Mixed

Sex
All

Total final enrolment
10

Key exclusion criteria
1. Pregnant
2. Other cancer

Date of first enrolment
01/04/2016

Date of final enrolment
01/03/2020

Locations

Countries of recruitment
United Kingdom

England

Study participating centre
University College London Hospitals NHS Foundation Trust
