Plain English summary of protocol

Background and study aims
Assessing axillary lymph node metastasis status and staging is crucial, but the accuracy of conventional clinical assessment methods is unsatisfactory. The researchers propose combining radiomics technology (to extract quantitative, and ideally reproducible, information from diagnostic images), machine learning algorithms and 3D visualization technology to construct a 3D visualization diagnosis and localization methods for axillary lymph nodes. This provides a new method for clinical axillary lymph node assessment of breast cancer.

Who can participate?
Female invasive breast cancer patients aged between 20-85 years old who had completed lung-enhanced CT and axillary lymph node dissection surgery.

What does the study involve?
Data will be retrospectively collected from all enrolled patients who underwent high-resolution thin-section enhanced CT of the lungs within 1 month before surgery. All patients had complete clinicopathological data, did not have distant metastases, and had not undergone neoadjuvant therapy (NAT).

What are the possible benefits and risks of participating?
A 3D visualization diagnosis and localization method will be constructed, which can effectively improve the predictive efficacy of assessing axillary lymph node status. Using medical records obtained from previous clinical visits for the study is consistent with minimal risk and will not adversely affect the rights or health of the participants.

Where is the study run from?
The Second Xiangya Hospital of Central South University.

When is the study starting and how long is it expected to run for?
January 2016 to January 2024

Who is funding the study?
The Science and Technology Innovation Program of Hunan Province (Grant No.2021SK2026).

Who is the main contact?
Prof. Wenjun Yi, yiwenjun@csu.edu.cn.

Study design

Single-center diagnostic test

Primary study design
Observational

Study type(s)
Diagnostic

Health condition(s) or problem(s) studied
Prediction of axillary lymph node metastasis in breast cancer patients

Interventions
Researchers will retrospectively collect data from invasive breast cancer patients who had completed lung-enhanced CT and axillary lymph node surgery. The researchers will construct a 3D axillary lymph node atlas using 3D visualization techniques. Researchers will localize and segment regions of interest (ROIs) from axillary lymph nodes, extract and select radiomic features, and construct axillary lymph node prediction models.

Intervention Type
Other

Primary outcome(s)
Predicting correct classification rate, sensitivity and specificity after axillary surgery measured using 3D visualization techniques to construct predictive models at one time point

Key secondary outcome(s))
Predicting misclassification rate, false-positive rate and false-negative rate after axillary surgery measured using 3D visualization techniques to construct predictive models at one time point

Completion date
31/01/2024

Eligibility

Key inclusion criteria
1. Underwent BC surgery at our hospital with postoperative pathology confirming invasive BC
2. Underwent axillary lymph node dissection (ALND) at our hospital
3. Completed a high-resolution, thin-section enhanced CT scan of the lung in our radiology department within one month before surgery
4. Had complete clinicopathological data

Participant type(s)
Patient

Healthy volunteers allowed
No

Age group
Mixed

Lower age limit
20 years

Upper age limit
85 years

Sex
Female

Total final enrolment
500

Key exclusion criteria
1. Had bilateral primary or metastatic bc
2. Received neoadjuvant therapy (nat) before surgery
3. Had incomplete or poor-quality CT scans, flat scans only, or scans conducted externally
4. Had distant metastatic lesions or concurrent other malignancies

Date of first enrolment
29/03/2023

Date of final enrolment
31/12/2023
