Plain English summary of protocol

Background and study aims

At the moment, for both colorectal and pancreatic cancer, clinical decisions are based mainly on two modalities: radiology scans and blood biomarkers (tumour markers), the latter being specific for different types of cancer (CEA for colorectal and CA19-9 for pancreatic cancer, respectively). What we see on scans and how high or not the tumour markers are, dictate the appropriate treatment path for each patient, which usually includes a combination of surgery and/or chemotherapy-radiotherapy. However, since cancer harbours different types of mutations, often patients do not respond to treatment as expected and there are significant delays until this is reflected either on radiology images or on tumour marker levels. Apparently, there is an ongoing delay in optimising patients' treatment, limited by the existing diagnostic modalities. Therefore, the key to improving patient care and outcomes is to open a door and gain insight into tumour biology.

Circulating tumour DNA (ctDNA) is a form of cell-free DNA (genetic material) that originates from tumour cells and is found in the bloodstream. Liquid biopsy, a method that involves the analysis of ctDNA, offers a minimally invasive alternative to traditional tissue biopsies. This technique allows for the detection and monitoring of cancer by analysing blood samples. This is a study on ctDNA in patients with a new diagnosis of pancreatic and colorectal cancer.

Who can participate?

All adults in NHS Tayside with the above new diagnosis

What does the study involve?

The researchers will monitor the ctDNA levels in the participants' bloodstream during their treatment and over the surveillance period with recurring peripheral blood samples.

What are the possible benefits and risks of participating?

The main benefits of the study will be to assess this biomarker as an adjunct to identify disease progression or recurrence more easily. There are no associated risks for the participants, however, any results will not be communicated to them until the end of the study and they will not affect the decision-making process regarding their treatment.

Where is the study run from?
Ninewells Hospital in Dundee, Scotland within NHS Tayside (UK)

When is the study starting and how long is it expected to run for?
April 2024 to October 2028

Who is funding the study?
NHS Tayside Charitable Foundation (UK)

Who is the main contact?
Mr Georgios Gemenetzi, Georgios.gemenetzi2@nhs.scot

Study information

Scientific Title
The Tayside Cancer Network (TAY.CA.N) Initiative: Utilisation of circulating tumour DNA (ctDNA) as a clinical biomarker for early detection of disease progression and recurrence in patients with pancreatic and colorectal cancer

Acronym
TAYCAN

Study objectives

The primary hypothesis of this proposal suggests that the presence and ctDNA in the peripheral circulation of patients with pancreatic and colorectal cancer fluctuates according to tumour burden and therefore is directly correlated with presence of disease. As a result it can be utilised as a biomarker for early detection of disease recurrence or progression.

Primary study design

Observational

Study design

Single-centre longitudinal observational cohort study

Study type(s)

Prevention, Screening

Health condition(s) or problem(s) studied

Disease progression and recurrence in pancreatic and colorectal cancer

Interventions

Eligible patients will be recruited in the study and will undergo further genomic testing of the acquired biopsies for diagnostic purposes to determine the genetic profile of the primary tumours and recurring peripheral venous blood sampling to assess the presence and burden of said mutations in the bloodstream.

Intervention Type

Other

Primary outcome(s)

ctDNA levels for cancer-specific mutations measured with next-generation sequencing (NGS) at baseline and every 2 months between treatment modalities, until proof of disease recurrence or patient death/loss to follow up

Key secondary outcome(s)

Measurement in days of the lead changes in ctDNA levels compared to evidence of disease recurrence on traditional biomarkers (CA19-9, CEA) and on imaging (CT, MRI)

Completion date

01/10/2028

Eligibility

Key inclusion criteria

1. All patients with a new diagnosis of pancreatic or colorectal cancer between ages 18-80 years
2. A cohort of healthy individuals (no previous cancer diagnosis) will be the control group and

will need to provide a sample of peripheral blood samples to prove the lack of mutant genetic material in their bloodstream

Participant type(s)

Healthy volunteer, Patient

Healthy volunteers allowed

No

Age group

Mixed

Lower age limit

18 Years

Upper age limit

80 Years

Sex

All

Total final enrolment

0

Key exclusion criteria

1. For participants with a pancreatic or colorectal cancer diagnosis: past medical history of a different primary malignancy
2. For healthy participants: previous diagnosis of cancer

Date of first enrolment

01/05/2025

Date of final enrolment

01/05/2027

Locations
